Activity 1. Basic recursive models.

- **A brief explanation for each of the given classes indicating how you calculated the complexity of that class.**

We have to take into consideration that a is the number of subproblems, b is the constant by which we reduce the subproblem, and k is the complexity of the code when excluding the recursive calls, and also, for divide and conquer by subtraction, we consider the following:

➤ Complexity

- $O(n^k)$ if $a < 1$ (never happens)
- $O(n^{k+1})$ if $a = 1$
- $O(a^{n \div b})$ if $a > 1$

With this information we can compute the complexity of the classes having a , b , and k :

Subtraction 1: $a=1$, $b=1$ and $k=0$. So the complexity is $O(n)$

Subtraction 2: $a=1$, $b=1$ and $k=1$. So the complexity is $O(n^2)$

Subtraction 3: $a=2$, $b=1$ and $k=2$. So the complexity is $O(2^n)$

For divide and conquer by division we consider this other one:

Algorithmics	Student information	Date	Number of session

	Name: Stelian Adrian		

➤ Complexity

- $O(n^k)$ if $a < b^k$
- $O(n^k * \log n)$ if $a = b^k$
- $O(n^{\log_b a})$ if $a > b^k$

Division 1: $a=1$, $b=3$ and $k=1$. So the complexity is $O(n)$

Division 2: $a=2$, $b=2$ and $k=1$. So the complexity is $O(n \log n)$

Division 3: $a=2$, $b=2$ and $k=0$. So the complexity is $O(n)$

- **A brief explanation for each of the two new classes indicating how you calculate the complexity to get the requested one.**

Using the same images as before:

For Subtraction4, for getting a complexity $O(3^{n/2})$, we see that the exponential complexity is obtained when $a > 1$, and looking at the arguments, we can deduce that b should be equal to 2 and $a = 3$. The value of k is not relevant. For getting $b = 2$ we reduce the value of n by 2 in every recursive call, and to get $a = 3$ put 3 recursive calls to the method.

For Division4, for getting a complexity $O(n^2)$, with a number of subproblems $a = 4$, we have to make sure that $a < b^k$, and that $k = 2$, for that purpose we can use for example $b = 3$, as it satisfies the condition.
